
Inverter input voltage bootstrap

What is a bootstrap output power supply circuit?

The bootstrap output power supply circuit is used to power the top-bridge gate drives by making use of the inverter operating conditions to store and deliver the necessary power charges. Figure 2 shows a bootstrap circuit that provides power to the ACPL-H342/K342 gate-drive optocouplers.

Which voltage is applied between the resistor and bootstrap capacitor?

The voltage shown in the graph is the one applied between the resistor. There are some issues in the circuit. The bootstrap capacitor will charge to 315 V when low side output MOSFET is activated, so it will destroy high side MOSFET's gate. The negative terminal of power supply +15 V for bootstrapping must be connected to -300 V supply.

How does a bootstrap capacitor work?

The bootstrap capacitor will charge to 315 V when low side output MOSFET is activated, so it will destroy high side MOSFET's gate. The negative terminal of power supply +15 V for bootstrapping must be connected to -300 V supply. Also the low side level shifter will force VGS of low side MOSFET to 300 V when it is activated.

How does a bootstrap resistor work?

The bootstrap resistor must be able to withstand the short period of high power dissipation during the initial charging sequence of the bootstrap capacitor. The gate current and the appropriate power of the voltage supply depend on the operating frequency, bias control voltages, and total gate charge.

INTRODUCTION This application note provides practical guidelines for designing with the Motion SPM 5 Series power modules. This series of Intelligent Power Modules (IPM) for 3-phase ...

At the same time, the internal logic turns on the open-drain output and holds it on until the SD voltage goes below the VSSD threshold and the toc time is elapsed. The driver outputs restart ...

Considerations on bootstrap circuitry for gate drivers Driving a half-bridge based on N-channel MOSFETs or IGBTs requires providing to the high-side switch a gate voltage greater than the ...

Bootstrap voltage (VBS) will gradually decrease due to the circuit current of the GD IC during the pause state of inverter operation. The VBS drop ratio will be estimated by ...

This is a second on-chip LDO, which can be used to bias the chip. When the input voltage is consistently high, it is more efficient to produce the biasing voltage by stepping down the ...
